

ABOUT MORTALITY DATA FOR GERMANY

By Rembrandt Scholz, Dmitri Jdanov, Eva Kibele, Pavel Grigoriev, Sebastian Klüsener

Last revised: December 04, 2018

GENERAL

From 1949 to 1990, Germany was split into two parts, which were referred to as the Federal Republic of Germany (FRG) and the German Democratic Republic (GDR). For the period since the German reunification, this report distinguishes between “East Germany”, which corresponds to the area of the former GDR, and “West Germany”, which corresponds to the area of the former FRG.

Germany is a federal republic consisting of 16 states (referred to as *Länder* or *Bundesländer*). In the Human Mortality Database (HMD), the following *Länder* combine into West Germany: Baden-Württemberg, Bayern, Bremen, Hamburg, Hessen, Niedersachsen, Nordrhein-Westfalen, Rheinland-Pfalz, Saarland, and Schleswig-Holstein, as well as West Berlin. East Germany consists of the following *Länder*: Mecklenburg-Vorpommern, Brandenburg, Sachsen-Anhalt, Sachsen, Thüringen, and East Berlin. This division was maintained in the HMD until 2015. Since 2016, West Berlin is included in East Germany and consequently excluded from the territory of West Germany.

The official statistical system in Germany

There is close co-operation between the Federal Statistical Office and the statistical offices of the *Länder*. In Germany, the Federal Government and the *Länder* share the responsibility for the collection and production of official statistics, following the tradition of the Federal Republic of Germany. The Federal Statistical Office compiles federal results from the *Länder* data and publishes them; the statistical offices of the *Länder* publish their results separately. There is a clear division in the dissemination of statistical data between the Federal and the *Länder* offices. The Federal Statistical Office publishes data for Germany as a whole with a geographical breakdown at the level of the *Länder* only. The publication of regional data at or below the *Länder* level, even down to the level of local administrations, is the task of the statistical offices of the *Länder*.

Between 1876 and 1945, vital registration statistics in all parts of Germany was based on the same law (the *Personenstandsgesetz*). Census taking has been harmonized across the member states of the German Empire since 1925. Previously, most of the states had counted the *de facto* population, while the Saxony and the Hanseatic city states of Hamburg, Lübeck, and Bremen had reported the *de jure* population (Lee and Schneider, 2005). The “*Personenstandsgesetz*” was slightly modified between 1945 and 1990, with separate practices in the FRG and the GDR. Since October 3rd, 1990, the official day of reunification, population statistics in both parts of Germany have been collected following the same laws.

Differences in population statistics between the two parts of Germany prior to 1990 existed in the definitions used for live births and for the resident population. In the GDR,

the term “live birth” was used when two signs of life occurred, while in the West only one sign was required. The GDR only included in the resident population people who had been living in the country for at least six months, whereas in FRG the resident population included all persons in residence.

DATA SOURCES

All of the raw data used for the Human Mortality Database (HMD) originate from statistical data provided by the Federal Statistical Office in Wiesbaden and the Statistical Offices of the German states. The HMD Input Database (Input DB) includes death, birth and population counts for all years since 1990.

TERRITORIAL COVERAGE

There has been no territorial change since 1990.

DEATH COUNT DATA

Coverage and Completeness

The annual statistics include all registered deaths of residents of Germany (source: laws for the registration of births, marriages and deaths). We are not aware of any substantial misreporting in the death statistics. The quality of age reporting is high as since 1876 birth and death registration has been conducted by the registry office in all parts of Germany, and death registration has been requiring a birth certificate from the registry office.

BIRTH COUNT DATA

Coverage and Completeness

The definition of a “live birth” has changed over time:

- In 1991-1993: Newborn child whose breathing *or* heartbeat started after complete separation from the mother independent of cutting the umbilical cord and delivery of the placenta, and whose body weight was no more than 1,000 grams.
- Since 1994 : Newborn child whose breathing *or* heartbeat started after complete separation from the mother independent of cutting the umbilical cord and delivery of the placenta, and whose body weight was not more than 500 grams.

Prior to 1994, stillbirths were under-estimated compared with the following period because the minimum birth weight for classification as a stillbirth rather than as a spontaneous abortion (i.e., miscarriage) changed on March 31st, 1994, from 1,000 grams to 500 grams.

POPULATION COUNT DATA

Coverage and completeness

Official population estimates are based on census counts. Between census years, the birth, death, and migration counts are used by the Federal Statistical Office in Wiesbaden and the Statistical Offices of the German states to calculate the population on the last day of each year (December 31st).

In the FRG, the last census prior to reunification (in 1990) took place on May 25th, 1987. In the former GDR, it was conducted on December 31st, 1981. The population register was

already established in East Germany in the 1970s. The results of GDR census of 1981 revealed high quality of population register as the difference between these data sources turned out to be fairly small (about 20 thousand people). This population register was used as the basis for an enumeration conducted in East Germany on October 3rd, 1990, the official day when West and East Germany were reunited. The population register in the East was closed in 1992 because it was not compatible with the rules on data protection in the FRG. In the time period after 1988, population movement between West and East Germany was very intense, particularly in the years around the re-unification. However, the first census after unification was carried out in 2011 only. This was the first official register-based census, and it is disputed whether such a procedure can deliver results of the same quality as a traditional census (Coleman, 2013). For an overview on the potential deficiencies of the 2011 census see Scholz and Kreyenfeld (2016). That it was quite challenging to implement a register-based census in Germany is also underlined by the fact that the Federal Statistical Office decided not to use the officially published census results by age and sex as the basis for post-censal population estimates. Instead, a modified version of the estimates was published, which used additional statistical information (see Kaus and Mundil-Schwarz, 2015). Like the Federal Statistical Office, for the HMD calculations we decided to rely on the modified official census data.

The difference between the old population estimates produced earlier by the Federal Statistical Office in Wiesbaden and the Statistical Offices of the German states and the population estimates based on the new census of 2011, as obtained for the 1st of January 2012, is quite substantial. There were actually 977,000 fewer males and 539,000 fewer females compared to the previously published official population estimates.

DATA QUALITY ISSUES

Quality of data on population counts

As mentioned above, the differences between the population estimates constructed from the most recent census of 2011 and those constructed from the former censuses of 1981 (East Germany) and 1987 (West Germany) are quite substantial. Unfortunately, the Federal Statistical Office decided not to recalculate back the population estimates by age and sex for the complete inter-censal period. Some of the discrepancy between the two series of estimates arises in part from the massive internal and international migration flows experienced by Germany in the late 1980s and in the 1990s due to the fall of the Iron Curtain and German reunification. In consequence, the standard HMD inter-censal method, which assumes that migration is uniformly distributed across the inter-censal period is not applicable in this case.

Another problem is related to substantial efforts by the statistical office to improve its estimation of population by cleaning its registers in the years prior to the 2011 census. This was done with the help of local (regional) statistical offices which were instructed to make sure that all out-migrants had been de-registered and that no one was registered in two different areas simultaneously, using alternative sources of information such as tax records. Without these prior cleaning activities, the differences between the population estimates based on the former censuses and those based on the 2011 census would

have been even larger. Unfortunately, these adjustments were only taken into account in the year when the error was detected while the undocumented outmigration event or a multiple registration might have occurred years or decades before. Data cleaning operations were implemented by the State Statistical Offices in various degrees throughout the inter-censal period, but two periods witnessed substantial corrections: 2004 and 2008–2010. To our knowledge, information about the exact number of individual removed from the registers and the exact dates of the removals from the resident population counts is unknown.

The Syrian refugee crisis and the massive migration flow into Germany during the most recent years has had a notable impact on the size and age-structure of the population. According to the 2014 official estimates, net migration in Germany reached 550,000 and it increased again in 2015, reaching one million (with two million arrivals and one million departures (Statistisches Bundesamt, 2017)). Most of the migrants were young males with a sex ratio particularly skewed in their favor in 2015.

Intensive in-migration eventually affected the quality of population estimates at younger ages because of problems related to the registration of refugees and asylum seekers. Though migrants are required to be registered, official estimates of the number of refugees are affected by an under-coverage which is difficult to quantify, though issues of multiple counts have also been raised as migrants could have registered each time they moved to a new area within the country¹.

REVISION HISTORY

Changes with the December 2017 Revision

Since January 2016, the territory of East Germany includes the city of Berlin.

Changes with the December 2017 Revision

Life tables: All life tables have been recalculated using a modified methods protocol. The revised protocol (Version 6) includes two changes: 1) a more precise way to calculate a_0 , the mean age at death for children dying during the first year of life and 2) the use of birth-by-month data (where and when available) to more accurately estimate population exposures. These changes have been implemented simultaneously for ALL HMD series/countries. For more details about these changes, see the revised Methods Protocol (at <http://v6.mortality.org/Public/Docs/MethodsProtocol.pdf>), particularly section 7.1 on Period life tables and section 6 and Appendix E, on death rates. The life tables calculated under the prior methods (Version 5) remain available at v5.mortality.org but will not be further updated in the future.

¹ The Statistical Office acknowledges the problems related to refugee registration, stating that: "It must be assumed that the 2015 figures on people seeking refuge are affected by undercoverage which cannot be quantified because the registration authorities were unable to register all people seeking refuge in a timely manner. In addition, double counting may have occurred because of false register entries in connection with the distribution of people seeking refuge within Germany" (https://www.destatis.de/EN/FactsFigures/_CrossSection/Refugees/Refugees.html)

Changes with April 2017 Revision

We carried out some further refinement to the adjustment implemented with the previous revision to construct population estimates for the inter-censal period (Klüsener et al., 2018). This modification resulted in very minor changes in population size (predominantly at ages above 80 years), and had a negligible impact on mortality rates.

Changes with April 2016 Revision

The inter-censal population estimates for the period 1987–2011 have been revised to account for the results of the last census. For this we used a country-specific method. The adjustments to the population estimate numbers were implemented in two main steps. In the first step, we accounted for the corrections made by the statistical offices of Germany to their population estimates prior to the 2011 census. This adjustment accounted for errors that occurred due to multiple registrations and undocumented out-migration events. The adjustments assumed that when they were implemented (in 2004 and in 2008–2010), all outmigration rates above an ‘expected’ level of outmigration could be attributed to the adjustments made by the statistical offices. Using a simple spline interpolation we estimated the ‘expected’ migration rates by cohort. The difference between ‘expected’ and ‘observed’ events in years 2004 and 2008–2010 was assumed to reflect artificial migration counts, which was then added to the accumulated error. In the second step, this error was redistributed by cohort and by sex assuming that it had accumulated in a linear manner over the inter-censal period. For more details see Data Quality Issues section and Klüsener et al., 2018).

In the previous revisions we applied an adjustment factor to the population older than 90 years because of the low quality of population estimates at advanced ages (Scholz and Jdanov, 2007). The new official estimates for the population at ages 90+ years (based on the 2011 census) are extremely close to the alternative HMD estimates derived previously from the 1981 and 1987 census and vital statistics using the aforementioned correction factor. As indicated in Figure 1, the difference between the new estimates and the previous HMD estimates is close to zero, while the difference between the previous HMD estimates and the previous official estimates used to be large, particularly among males in Western Germany (see more details about the latter comparison in Jdanov, Scholz, Shkolnikov, 2005).

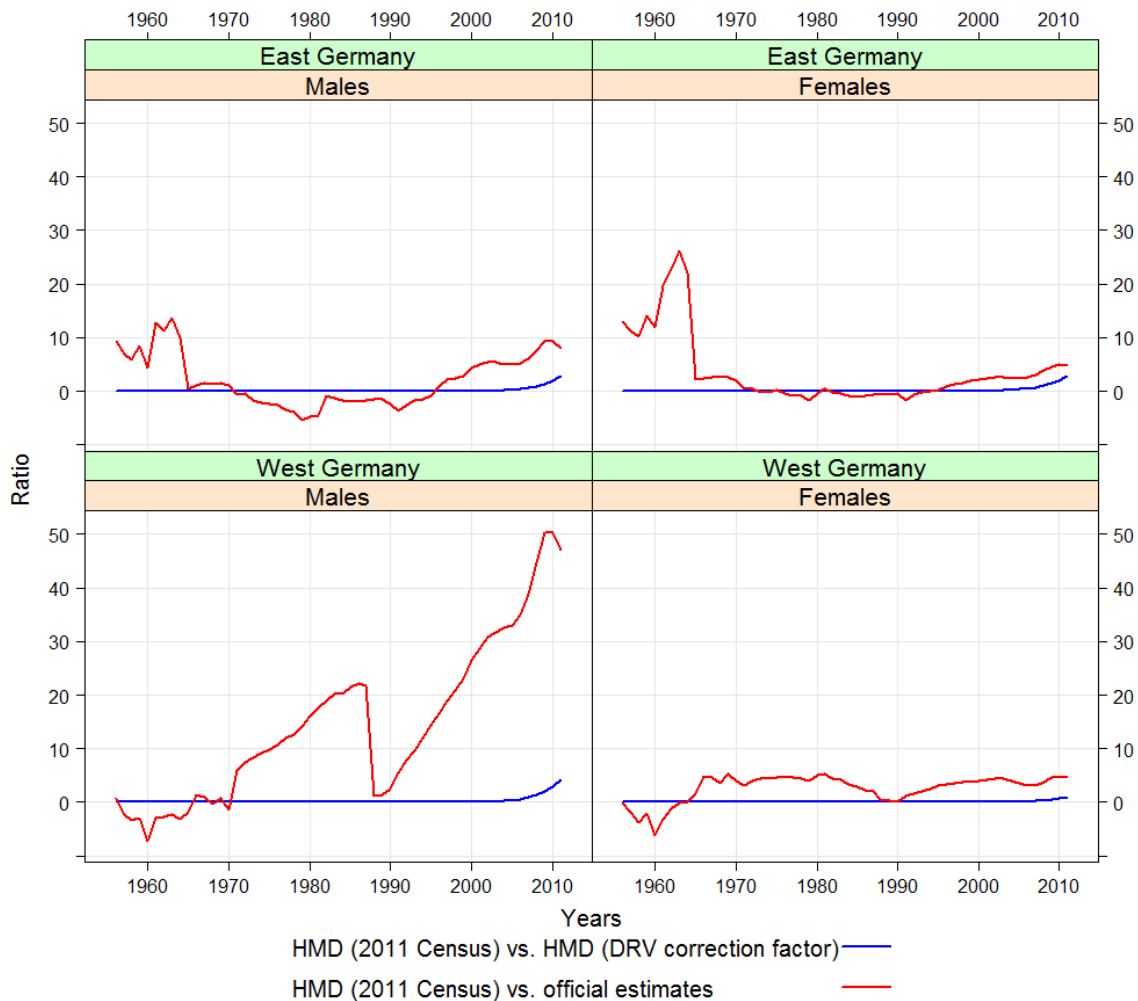

Figure 1. Relative difference (per cent): HMD (2011 Census) vs. HMD (DRV correction factor) and HMD (2011 Census) vs. old official population estimates; ages 90+

ACKNOWLEDGEMENTS

We would like to thank: Walter Becker, Jutta Gebhardt, Hans-Peter Bosse, Dieter Emmerling, Gisela Papaja-Yadegari, and Anja Conradi-Freundschuh at the Federal Statistical Office Wiesbaden; and Anita Depner, Beate Koehn, Viola Kraemer, Rolf Paletta, R. Hopf-Engelk, and Monika Zornik at the Statistical Office of Berlin for their kind help and assistance in compiling the German data. We express our special gratitude to Bettina Sommer (Federal Statistical Office) and Juergen Paffhausen (Statistical Office of Berlin) for very useful comments. We thank the staff at the research data center of the Deutsche Rentenversicherung (DRV) for the provision of pension statistics.

APPENDIX 1:

DESCRIPTION OF THE ORIGINAL DATA USED FOR HMD CALCULATIONS

DEATHS

Period	Type of Data	Age Grouping	Comments	RefCode(s) [†]
1990-2000	Annual number of deaths to residents by sex, age and birth cohort (Lexis triangles)	0, 1, 2, 3, ... maximum age attained		5, 6, 7, 14
2001-2017	Annual number of deaths to residents by sex, age and birth cohort (Lexis triangles)	0, 1, 2, 3, ... maximum age attained		15, 16, 24, 25, 28, 31, 35, 38, 41

POPULATION

Period	Type of Data	Age Grouping	Comments	RefCode(s) [†]
1990-2011	Annual population estimates (as of December 31 st) by sex and age	0, 1, 2, 3, ...95+	Reconstructed data	33
2012-2017	Annual population estimates (as of December 31 st) by sex and age	0, 1, 2, 3, ...100+		34 37 40

BIRTHS

Period	Type of Data	Comments	RefCode(s) [†]
1990-2017	Annual live birth counts by sex		12, 13, 20, 21, 22, 23, 29, 32, 36, 39, 42

BIRTHS BY MONTH

Type of data: Annual live birth counts by month

Period covered: 1946–2017

RefCodes: 43, 44

† The reference code is used to link 'Input Data' with the primary data source
